作业3: 聚类

- 谱聚类算法的流程:
 - (1) 计算Laplacian矩阵;
 - (2) 对Laplacian矩阵进行特征值分解,取最小的k个特征值,得到对应的特征向量 $u_1, u_2, ..., u_k$,得到 $S = [u_1, u_2, ..., u_k] \in R^{N \times k}$;
 - (3) 令 $S^T = [v_1, v_2, ..., v_N] \in R^{k \times N}$,对 $\{v_1, v_2, ..., v_N\}$ 进行k-means聚类得到结果。
- Modularity maximization的流程: 只需将谱聚类算法中的 Laplacian矩阵换为Modularity矩阵(P55)。

- Cluster WebKB-Cornell dataset into 3 clusters using ratio cut spectral clustering (5 points) and modularity maximization (5 points).
- You can use pyg, numpy and scikit-learn's implementation of k-means algorithm. Do not directly call its spectral clustering function.
- Number of eigenvectors used for clustering is 3.
